Nowadays, creating a website has become a very feasible task, as opposed to the early stages of the internet, thanks to many of the existing tools that have appeared throughout the years.

Many alternatives exist, offering different possibilities and requiring different levels of expertise but nowadays almost anyone can create a web page. Three main possibilities are the most used when it comes to developing a website:

On one hand there is coding. It requires knowledge in programming languages such as HTML, CSS and Javascript. These are used for the layout of the website, called FrontEnd. HTML and CSS are used to define the structure, style and content of the web page and Javascript adds functionalities and interactivity to this layer. When it comes to data and inner functionalities, on the other hand, many other possibilities a BackEnd is needed. This one gives database support to the web page [1].

While coding offers a more versatile option for creating websites, it requires knowledge in the aforementioned fields, and can be a difficult task to tackle unless working with a team..

The second one, using an IDE, such as Netbeans or Visual Studio, requires some knowledge of the programming languages, but has plenty of tools to work with that will allow a programmer to create a web page by placing elements, such as boxes and text panels. Using an IDE offers the control of coding while offering a visual method to intuitively create the design.

Finally, there are web page builders. This method is significantly easier than the previous and allows the user to develop a website without having to write code. Some of the most famous sites that offer this tool are Wix or Squarespace, for example.

This tools allow chosing different templates, adding basic functionalities and updating the content, only a few clicks away. Thus, while using a web page builder yields faster results and requires, generally speaking, less effort, full control over the website is lost, but it is a tool mainly targeted at beginners [3].

After the web itself is created, a hosting server is needed: the physical location where the web page will be stored. While web builders usually offer this service, the other mentioned methods don't, and a host will be needed. It is usually provided by domain registrars.

Domain registrars are companies that allow the user to purchase a domain name (e.g. google.com, youtube.org, etc), the name by which web page will be identified and accessed. Because of this, it has to be unique and usually requires a registration fee [2].

To summarize, creating a web page it is a matter of time and effort, and when it comes to deciding which methods will be used for its development, knowledge and experience in the field have to be taken into consideration as well as resources (time and money), as all alternatives offer different advantages and disatvantages depending on the situation. It's not a one-step process either, though, as a domain and a hosting are needed too, and the most important part: updating the website and andvertising it (or not), depending on its purpose.
